

Background

In recent years, online recruitment has become a major hiring channel for companies. Recruitment platforms have evolved from simple job listings and search functions to algorithm-based matching systems, which use data analysis to improve matching efficiency between candidates and job opportunities (Eastmoney, 2025).

However, both job seekers and employers still face several challenges in the current recruitment process. Job seekers often struggle to find suitable positions, while employers face difficulties in identifying qualified candidates efficiently. In addition, issues such as mismatches between job requirements and candidate skills, lack of information, data privacy risks, and low communication efficiency further reduce recruitment effectiveness. The third parties make the system less trustworthy.

While the development of online recruitment platforms, currently existing systems still have a lot of limitations. Most platforms still rely on basic search and filtering functions and lack intelligent matching mechanisms, which makes it more difficult to achieve accurate and efficient job matching.

To address these issues, this project proposes the development of an Intelligent Talent Matching Platform. The system aims to improve the efficiency of recruitment by providing a two-way matching mechanism that recommends suitable jobs to candidates and identifies relevant candidates for employers.

This proposal suggests creating an Intelligent Talent Matching Platform to solve these problems. The system aims to improve recruitment efficiency by matching candidates with suitable jobs and helping employers find skilled candidates.
